## Press release

**PRESS EMBARGO ends: Thursday, October 16, 2014**

## Informative visit to the toilet

**German Primate Center (DPZ) study shows: Lemurs use communal latrines as information exchange centers**

*Göttingen, October 14, 2014.* Emily loves Justin, Stop global warming, Two more weeks till I graduate! The exchange of information in public toilets is widespread. It also occurs in the world of white-footed sportive lemurs. Only instead of writing on the walls, they use scent-marks in order to communicate with their own kind. In their recently published study, Iris Dröscher and Peter Kappeler from the German Primate Center (DPZ) have found that, in particular, the urine left on latrine trees serves as a method to maintain contact to family members. It also serves as a means to inform an intruder that there is a male that will defend his partner. Latrines serve as information exchange centers and promote social bonding in territorial nocturnal animals that do not live in closely-knit groups (*Behavioral Ecology and Sociobiology*, 2014).

In the animal kingdom, the use of latrines, which serve as specific locations for urination and defecation, is a common occurrence. Because little is known about why primates in particular use the same latrines over and over, the researchers set out to investigate this phenomenon among white-footed sportive lemurs (*Lepilemur leucopus*) in southern Madagascar. Do they hint to others that they want to defend their mate or territory? Or, do they indicate the fertility of the female? Or do they promote exchange of information within a group and support social bonding? To answer these questions, the researchers wanted to establish where such latrines were found, and if they were used differently between seasons, and between individuals of different ages and sexes. In the process, Dröscher and Kappeler spent over 1,000 hours watching the toilet habits of 14 radio-collared adult sportive lemurs.

### Social bonding thanks to latrines

White-footed sportive lemurs are nocturnal tree-dwellers that are found exclusively in southern Madagascar. They live together in families consisting of parents and their offspring. Even though the family members share a common territory, the individuals do not interact much. Neither do pair-partners sleep in the same tree nor do they associate while foraging. But what they have in common are latrines that are located in the core of their territory. All members of the family visit the same latrines for defecation and urination. Dröscher and Kappeler believe the latrines are a way in which to maintain familiarity and social bonding among members of a social unit, who otherwise have very little contact with each other. Such

scent signals are picked up from urine that stains the tree trunks rather than feces that accumulate on the ground under the trees.

### **Message: Defending my partner!**

Males visited the latrines more often during nights, when an intruder invaded the territory. In addition, the males placed scent marks from their specialized anogenital glands preferentially in latrines. “This indicates that latrine use in this primate species should also be connected to mate defense,” says Iris Dröscher, a PhD student at the German Primate Center.

### **Latrines as reliable centers of information exchange**

“Scent marks transmit a variety of information such as sexual and individual identity and may function to signal an individual’s presence and identity to others,” says Dröscher. “Latrines therefore serve as information exchange centers of individual-specific information.”

“Especially nocturnal species with limited habitat visibility and low interindividual cohesion profit from predictable areas for information exchange to facilitate communication”, says Peter Kappeler, head of the Department for Behavioral Ecology and Sociobiology at the DPZ. “The white-footed sportive lemur has found these information centers by means of latrine use.”
